## 1 introduction

Traveling salesman problem(TSP) asks the following question: Given a list of cities and distances between each pair of cities, what is the shortest possible route that visits each city exactly once and returns to the origin city?

We can reformulate the problem as follows: In essence, this is to find a circuit with the smallest weight in a weighted undirected graph. And we can translate it into a constrained optimization problem via branch and bound algorithm using both lazy cut and user cut.

We define the decision variable  $x_{ij}$  as

$$x_{ij} = \begin{cases} 1 & \text{if goes from i to j} \\ 0 & \text{otherwise} \end{cases} \quad (i, j) \in A$$

where  $A$  is the set of edges.

The objective function can be written as

$$\min \sum_{(i,j) \in A} c_{ij} x_{ij}$$

.Considering the balance between input and output of each node, we have the first two constraints:

- $\sum_{j \in V, (i,j) \in A} x_{ij} = 1 \quad \forall i \in V$
- $\sum_{i \in V, (i,j) \in A} x_{ij} = 1 \quad \forall j \in V$

where  $V$  is the sets of node.

However, if we only impose the two constraints above, the solution can be suffered from sub-tours, which destroy the optimality.

In order to eliminate subtours, we impose the following constraint:

$$\sum_{j \notin S, i \in S, (i,j) \in A} x_{ij} \geq 1 \quad \sum_{i,j \in S, (i,j) \in A} x_{ij} \leq |S| - 1 \quad \forall S \subset V, 2 \leq |S| \leq n - 1$$

which means any node subset has edges less than its cardinality and must have edges connecting its complement set. We need to eliminate subtours through **lazy cut** and **user cut** attempting to add this constraint dynamically since numbers of this kind of constraints are  $O(n^2)$ .

It is easy to make a callback via lazy cut, however, we need to have a deeper insight into user cut solving a minimum cut problem:

If we denote edge  $ij$  to be chosen or not( we do not discriminate  $ij$  and  $ji$ ) by  $x_{[ij]}$ , leading to  $\frac{n(n-1)}{2}$  variables. We have the following problem

$$\begin{aligned} \min & \sum_{i,j \in V} c_{[ij]} x_{ij} \\ \text{such that} & \sum_{j \in V, j \neq i} x_{[ij]} = 2 \quad \forall i \in V \\ & x_{[ij]} \in \{0, 1\} \end{aligned}$$

So that we need to find a set  $S_1$  such that  $\sum_{i \in S_1, j \notin S_1} x_{[ij]} \geq 2$ . It is intuitive to consider partitioning the nodes into two disconnected sets with weight of edges between two set attaing the minimum. As a result it will be easier to find the subtour violating the third constraint.

**Figure 1.** minimum cut

## 2 Input and output

### 2.1 Lazy Cut

Lazy cut is realized in the file "Project 1-lazy.ipynb" and please compile the function **distance**, **subtour**, **subtoureli** first.

Considering the data set uploaded by TA, we just write the following codes(using example of 20 points):

```
load C:/Users/mac/Desktop/Optimization/TSP data/20_0.py
```

As for the output, we refer the following codes:

```
city=list(range(len(points)))
coordinates={} ##dictionary
for i in city:
    coordinates[i]=(float(points[i][0]),float(points[i][1]))
dist={(c1,c2):distance(c1,c2) for c1,c2 in combinations(city,2)}
m=gp.Model()
vars=m.addVars(dist.keys(),obj=dist,vtype=GRB.BINARY,name='x')
for i,j in vars.keys():
    vars[j,i]=vars[i,j]
cons=m.addConstrs(vars.sum(c,'')==2 for c in city)
m._vars=vars# vars see establish model
m.Params.lazyConstraints=1
%time m.optimize(subtoureli)
vals=m.getAttr('x',vars)
selected=gp.tuplelist((i,j) for i,j in vals.keys() if vals[i,j]>0.5)
tour=subtour(selected)
assert len(tour)==len(city)
tour
```

where **function distance** calculates Euclidean distance between points. **Function subtoureli** is the function(main) to optimize. Finally, we use **function subtour** to get the optimal route and **assert len(tour)==len(city)** is to test whether the optimal route is feasible and the tour is ( using the example of 100\_2): 0,27,23,49,9,72,13,35,82,84,25,41,43,69,34,4,17,74,76,1,87,48,30,66,3,79,18,97,77,32,38,52,11,99,36,83,7,29,53,40,55,45,75,94,5,33,80,19,90,2,63,6,64,15,89,51,91,96,92,78,26,56,57,54,65,37,85,39,10,81,95,24,20,86,71,16,73,68,93,58,21,59,44,70,61,22,46,31,8,12,47,50,42,60,67,14,98,62,28,88. (This result can be seen in the codes I upload).

## 2.2 User Cut

User cut is realized in the file "project-user.ipynb" in the file "project 1-user cut" and please compile the function **ipTSP**(the main function) first.

As for the input, we use the following codes to change the data structure(changing list into dictionary):

```
from tspData.tsp20_2 import points
a = list(range(len(points)))
points_dict=dict(zip(a,points))
```

Then for output, we singly use the main function **ipTSP**:

Nodes		Current Node		Objective Bounds			Work	
Expl	Unexpl	Obj	Depth	IntInf	Incumbent	BestBd	Gap	It/Node Time
0	0	5.24567	0	12	-	5.24567	-	0s

```

where **function distance** calculates the distance between points. And we also display the example of 100\_2:0,88,28,62,98,14,

67,60,42,50,47,12,8,31,46,22,61,70,44,59,21,58,93,68,73,16,71,86,20,24,95,81,10,39,85,37,65,54,57,56,26,78,92,96,  
91,51,89,15,64,6,63,2,90,19,80,33,5,94,75,45,55,40,53,29,7,83,36,99,11,52,38,32,77,97,18,79,3,66,30,48,87,1,76,74,  
17,4,34,69,43,41,25,84,82,35,13,72,9,49,23,27,0.(This result can also be seen in the codes I upload.)

In fact this result is the same as the result in Lazy cut where the only difference is the ergodic order.

### 3 Comparison between User Cut and Lazy Cut

Although intuitively, the user cut should be faster than lazy cut, the fact is that lazy cut always achieves the solving time nearly zero while user cut has a volatile solving time. Now I demonstrate those facts by displaying part of outputs.(See the figures at the top and bottom of this page)

From all these comparisons, we realize that user cut does not necessarily help solve the problem faster. Instead, solving time of user cut can change volatily, from which we can see that in 80

Nodes		Current Node		Objective Bounds			Work	
Expl	Unexpl	Obj	Depth	IntInf	Incumbent	BestBd	Gap	It/Node Time

Fig. 7. 80\_0 User 100s

points the time is 100 seconds while in 100 points the time is 6 seconds. However, for all the problems we display (and all problems in data sets TA provided), solving time of lazy cut is always nearly 0 seconds.

In summary:

- Solving time of user cut is more volatile than lazy cut and user cut is not necessarily faster than lazy cut.
- Solving time of lazy cut is more stable and is nearly 0 second for problems we met.
